

Gambling and Probability

CS231
Dianna Xu

1

The game of poker

- You are given 5 cards (this is 5-card stud poker)
- The goal is to obtain the best hand you can
- The possible poker hands are (in increasing order):
 - No pair
 - One pair (two cards of the same face)
 - Two pair (two sets of two cards of the same face)
 - Three of a kind (three cards of the same face)
 - Straight (all five cards sequentially – ace is either high or low)
 - Flush (all five cards of the same suit)
 - Full house (a three of a kind of one face and a pair of another face)
 - Four of a kind (four cards of the same face)
 - Straight flush (both a straight and a flush)
 - Royal flush (a straight flush that is 10, J, K, Q, A)

2

Poker probability: royal flush

- What is the chance of getting a royal flush?
 - 10, J, Q, K, and A of the same suit
- There are only 4 possible royal flushes
- Cardinality for 5-cards: $C(52,5) = 2,598,960$
- Probability = $4/2,598,960 = 0.0000015$
 - Or about 1 in 650,000

3

Poker probability: four of a kind

- What is the chance of getting 4 of a kind when dealt 5 cards?
 - 5 cards: $C(52,5) = 2,598,960$
- Possible hands that have four of a kind:
 - There are 13 possible four of a kind hands
 - The fifth card can be any of the remaining 48 cards
 - Thus, total is $13 \cdot 48 = 624$
- Probability = $624/2,598,960 = 0.00024$
 - Or 1 in 4165

4

Poker probability: flush

- What is the chance of a flush?
 - 5 cards of the same suit
- We must do ALL of the following:
 - Pick the suit for the flush: $C(4,1)$
 - Pick the 5 cards in that suit: $C(13,5)$
- Product rule: $C(13, 5) \cdot C(4, 1) = 5148$
- Probability = $5148/2,598,960 = 0.00198$
 - Or about 1 in 505
- Note that if you don't count straight flushes (and thus royal flushes) as a "flush", then the number is really 5108

5

Poker probability: full house

- What is the chance of getting a full house?
 - Three cards of one face and two of another face
- We must do ALL of the following:
 - Pick the face for the three of a kind: $C(13,1)$
 - Pick the 3 of the 4 cards to be used: $C(4,3)$
 - Pick the face for the pair: $C(12,1)$
 - Pick the 2 of the 4 cards of the pair: $C(4,2)$
- $C(13, 1) \cdot C(4, 3) \cdot C(12, 1) \cdot C(4, 2) = 3744$
- Probability = $3744/2,598,960 = 0.00144$
 - Or about 1 in 694

6

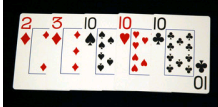

Inclusion-exclusion principle

- The possible poker hands are (in increasing order):
 - Nothing
 - One pair cannot include two pair, three of a kind, four of a kind, or full house
 - Two pair cannot include three of a kind, four of a kind, or full house
 - Three of a kind cannot include four of a kind or full house
 - Straight cannot include straight flush or royal flush
 - Flush cannot include straight flush or royal flush
 - Full house
 - Four of a kind
 - Straight flush cannot include royal flush
 - Royal flush

7

Poker probability: three of a kind

- What is the chance of getting a three of a kind?
 - That's three cards of one face
 - Can't include a full house or four of a kind
- We must do ALL of the following:
 - Pick the face for the three of a kind: $C(13,1)$
 - Pick the 3 of the 4 cards to be used: $C(4,3)$
 - Pick the two other cards' face values: $C(12,2)$
 - Pick the suits for the two other cards: $C(4,1)*C(4,1)$
- $C(13,1)*C(4,3)*C(12,2)*C(4,1)*C(4,1) = 54912$
- Probability = $54,912/2,598,960 = 0.0211$
 - Or about 1 in 47

8

Poker hand odds

- The possible poker hands are (in increasing order):

- Nothing	1,302,540	0.5012
- One pair	1,098,240	0.4226
- Two pair	123,552	0.0475
- Three of a kind	54,912	0.0211
- Straight	10,200	0.00392
- Flush	5,108	0.00197
- Full house	3,744	0.00144
- Four of a kind	624	0.000240
- Straight flush	36	0.0000139
- Royal flush	4	0.00000154

9

Probability axioms

- Let E be an event in a sample space S . The probability of the complement of E is:

$$p(\bar{E}) = 1 - p(E)$$
- Recall the probability for getting a royal flush is 0.0000015
 - The probability of *not* getting a royal flush is $1 - 0.0000015$ or 0.9999985
- Recall the probability for getting a four of a kind is 0.00024
 - The probability of *not* getting a four of a kind is $1 - 0.00024$ or 0.99976

10

Probability of the union of two events

- Let E_1 and E_2 be events in sample space S
- Then $p(E_1 \cup E_2) = p(E_1) + p(E_2) - p(E_1 \cap E_2)$

11

Probability of the union of two events

- If you choose a number between 1 and 100, what is the probability that it is divisible by 2 or 5 or both?
- Let n be the number chosen
 - $p(2|n) = 50/100$ (all the even numbers)
 - $p(5|n) = 20/100$
 - $p(2|n)$ and $p(5|n) = p(10|n) = 10/100$
 - $p(2|n)$ or $p(5|n) = p(2|n) + p(5|n) - p(10|n)$
 $= 50/100 + 20/100 - 10/100$
 $= 3/5$

12

When is gambling worth it?

- This is a *statistical* analysis, not a moral/ethical discussion
- What if you gamble \$1, and have a $\frac{1}{2}$ probability to win \$10?
- What if you gamble \$1 and have a $\frac{1}{100}$ probability to win \$10?
- One way to determine if gambling is worth it:
 - probability of winning * payout \geq amount spent per play

13

Expected Value

- The expected values of a process with outcomes of values a_1, a_2, \dots, a_n which occur with probabilities p_1, p_2, \dots, p_n is:

$$\sum_{i=1}^n a_i p_i$$

14

Expected values of gambling

- Gamble \$1, and have a $\frac{1}{2}$ probability to win \$10
 - $(10-1)*0.5+(-1)*0.5 = 4$
- Gamble \$1 and have a $\frac{1}{100}$ probability to win \$10?
 - $(10-1)*0.01+(-1)*0.99 = -0.9$
- Another way to determine if gambling is worth it: Expected value > 0

15

When is lotto worth it?

- In many older lotto games (Pick-6) you have to choose 6 numbers from 1 to 48
 - Total possible choices are $C(48,6) = 12,271,512$
 - Total possible winning numbers is $C(6,6) = 1$
 - Probability of winning is 0.0000000814
 - Or 1 in 12.3 million
- If you invest \$1 per ticket, it is only statistically worth it if the payout is $> \$12.3$ million

16

Powerball lottery

- Modern powerball lottery: you pick 5 numbers from 1-55
 - Total possibilities: $C(55,5) = 3,478,761$
- You then pick one number from 1-42 (the powerball)
 - Total possibilities: $C(42,1) = 42$
- You need to do both -- apply the product rule,
 - Total possibilities are $3,478,761 * 42 = 146,107,962$
- While there are many "sub" prizes, the probability for the jackpot is about 1 in 146 million
- If you count in the other prizes, then you will "break even" if the jackpot is \$121M

17

Blackjack

- You are initially dealt two cards
 - 10, J, Q and K all count as 10
 - Ace is EITHER 1 or 11 (player's choice)
- You can opt to receive more cards (a "hit")
- You want to get as close to 21 as you can
 - If you go over, you lose (a "bust")
- You play against the house
 - If the house has a higher score than you, then you lose

Blackjack table

19

Blackjack probabilities

- Getting 21 on the first two cards is called a blackjack
 - Or a “natural 21”
- Assume there is only **1 deck of cards**
- Possible blackjack blackjack hands:
 - First card is an A, second card is a 10, J, Q, or K
 - $4/52$ for Ace, $16/51$ for the ten card
 - $= (4 \cdot 16) / (52 \cdot 51) = 0.0241$ (or about 1 in 41)
 - First card is a 10, J, Q, or K; second card is an A
 - $16/52$ for the ten card, $4/51$ for Ace
 - $= (16 \cdot 4) / (52 \cdot 51) = 0.0241$ (or about 1 in 41)
- Total chance of getting a blackjack is the sum of the two:
 - $p = 0.0483$, or about 1 in 21
 - More specifically, it's 1 in 20.72

20

Blackjack probabilities

- Another way to get 20.72
- There are $C(52,2) = 1,326$ possible initial blackjack hands
- Possible blackjack blackjack hands:
 - Pick your Ace: $C(4,1)$
 - Pick your 10 card: $C(16,1)$
 - Total possibilities is the product of the two (64)
- Probability is $64/1,326 = 1$ in 20.72 (0.048)

21

Blackjack probabilities

- Assume there is **an infinite deck of cards**
- Possible blackjack blackjack hands:
 - First card is an A, second card is a 10, J, Q, or K
 - $4/52$ for Ace, $16/52$ for second part
 - $= (4 \cdot 16) / (52 \cdot 52) = 0.0236$ (or about 1 in 42)
 - First card is a 10, J, Q, or K; second card is an A
 - $16/52$ for first part, $4/52$ for Ace
 - $= (16 \cdot 4) / (52 \cdot 52) = 0.0236$ (or about 1 in 42)
- Total chance of getting a blackjack is the sum:
 - $p = 0.0473$, or about 1 in 21
 - More specifically, it's 1 in **21.13** (vs. 20.72)
- In reality, most casinos use “shoes” of 6-8 decks for this reason
 - It slightly lowers the player's chances of getting a blackjack
 - And prevents people from counting the cards...

22

Counting cards and Continuous Shuffling Machines (CSMs)

- Counting cards means keeping track of which cards have been dealt, and how that modifies the chances
- After cards are discarded, they are added to the continuous shuffling machine
- Many blackjack players refuse to play at a casino with one
 - So they aren't used as much as casinos would like

23

So always use a single deck, right?

- Most people think that a single-deck blackjack table is better, as the player's odds increase
 - And you can try to count the cards
- Normal rules have a 3:2 payout for a blackjack
 - If you bet \$100, you get your \$100 back plus $3/2 \cdot \$100$, or \$150 additional
- Most single-deck tables have a 6:5 payout
 - You get your \$100 back plus $6/5 \cdot \$100$ or \$120 additional
 - The expected value of the game is lowered
 - This **OUTWEIGHS** the benefit of the single deck!
 - And the benefit of counting the cards
 - Remember, the house always wins

24

Buying (blackjack) insurance

- If the dealer's visible card is an Ace, the player can buy insurance against the dealer having a blackjack
 - There are then two bets going: the original bet and the insurance bet
 - If the dealer has blackjack, you lose your original bet, but your insurance bet pays 2-to-1
 - So you get twice what you paid in insurance back
 - Note that if the player also has a blackjack, it's a "push"
 - If the dealer does not have blackjack, you lose your insurance bet, but your original bet proceeds normal
- Is this insurance worth it?

25

Buying (blackjack) insurance

- If the dealer shows an Ace, there is a $16/52 = 0.308$ probability that they have a blackjack
 - Assuming an infinite deck of cards
 - Any one of the "10" cards will cause a blackjack
- If you bought insurance 1,000 times, it would be used 308 (on average) of those times
 - Let's say you paid \$1 each time for the insurance
- The payout on each is 2-to-1, thus you get \$2 back when you use your insurance
 - Thus, you get $2 \cdot 308 = \$616$ back for your \$1,000 spent
- Or, using the formula $p(\text{winning}) \cdot \text{payout} \geq \text{investment}$
 - $0.308 \cdot \$2 \geq \1 ?
 - $0.616 \geq \$1$?
 - Thus, it's not worth it

26

Why counting cards doesn't work well...

- If you make two or three mistakes an hour, you lose any advantage
 - And, in fact, cause a disadvantage!
- You lose lots of money learning to count cards
- Then, once you can do so, you are banned from the casinos

27

So why is Blackjack so popular?

- Although the casino has the upper hand, the odds are much closer to 50-50 than with other games
 - Players following strategy will lose less than 1% on average luck
- Notable exceptions are games that you are not playing against the house – i.e., poker

28

Blackjack Strategy Chart

Hour Hand	Dealer's Up Card									
	2	3	4	5	6	7	8	9	10	A

Legend: H Hit, S Stand, D Double, P Split

29

Roulette

- A wheel with 38 spots is spun
 - Spots are numbered 1-36, 0, and 00
 - European casinos don't have the 00
- A ball drops into one of the 38 spots
- A bet is placed as to which spot or spots the ball will fall into
 - Money is then paid out if the ball lands in the spot(s) you bet upon

The Roulette table

- Bets can be placed on:

– A single number	1/38
– Two numbers	2/38
– Four numbers	4/38
– All even numbers	18/38
– All odd numbers	18/38
– The first 18 nums	18/38
– Red numbers	18/38

The Roulette table

Bets can be placed on:	Probability:	Payout:
– A single number	1/38	36x
– Two numbers	2/38	18x
– Four numbers	4/38	9x
– All even numbers	18/38	2x
– All odd numbers	18/38	2x
– The first 18 nums	18/38	2x
– Red numbers	18/38	2x

33

Roulette

- It has been proven that proven that no advantageous strategies exist
- Including:
 - Learning the wheel's biases
 - Casinos regularly balance their Roulette wheels
 - Using lasers (yes, lasers) to check the wheel's spin
 - What casino will let you set up a laser inside to beat the house?

34

Roulette

- Martingale betting strategy
 - Where you double your (outside) bet each time (thus making up for all previous losses)
 - It still won't work!
 - You can't double your money forever
 - It could easily take 50 times to achieve a final win
 - If you start with \$1, then you must put in $\$1 \times 2^{50} = \$1,125,899,906,842,624$ to win this way!
 - That's 1 quadrillion

35
