Lab 1

Analysis and thoughts
Linear Search

• Linear Search is a "MacGuffin"
  • The Maltese Falcon, The Grail, The Golden Fleece, Hitchcock
• Algorithmic improvements
• Empirical Studies
  • how to get good results
• Recursion
  • the Stack Overflow problem
  • Tail Call Optimization
Linear Search

• General Idea:
  • start at beginning of list
  • step through list comparing list item with target to find the location of target in list
  • return the target location or -1 if target not in list
  • Why -1?
**LinearSearch: Cormen's first Algorithm**

```plaintext
procedure linearSearch(A, n, x)

Inputs:
• A: An array (indexed from 0 onwards)
• n: the number of elements in A to search through
• x: the value being searched for.

Outputs: Either an index i for which A[i] = x, or a special value, -1
1. Set answer to -1.
2. For each index i=0 to n-1:
   a. If A[i] = x then set answer to i.
3. Return the value of answer
```

• For each item in the list, we have to
  • increment i
  • compare i to n
  • compare A[i] to x

• If we assume that each of these takes the same amount of time (t), then total time is
  • 3tN??
    • should "increment i" be 1 or 2 (or 3) operations?
    • should "compare i to n" be 1 or 3?
    • how many should compare A[i] to x be
      • 1, 3, 5, more?
Primitive Operations

even knowing this in a PL is hard

```java
public class BasicOps {
    public static void main(String[] args) {
        long tt = 0;
        long maxx = (1 * 1000000000);
        for (int j = 0; j < 10; j++) {
            long i = 0;
            long st = System.nanoTime();
            while (i < maxx) {
                i = i + 1;
            }
            long nd = System.nanoTime();
            System.out.format("%2d %d\n", j, (nd - st) / 1000);
            tt += (nd - st);
        }
        System.out.format("AV %d\n", (tt / 10000));
    }
}
Average time: 0.362 seconds
```

```java
public class BasicOps {
    public static void main(String[] args) {
        long tt = 0;
        long maxx = (2 * 1000000000);
        for (int j = 0; j < 10; j++) {
            long i = 0;
            long st = System.nanoTime();
            while (i < maxx) {
                i = i + 1;
                i = i + 1;
            }
            long nd = System.nanoTime();
            System.out.format("%2d %d\n", j, (nd - st) / 1000);
            tt += (nd - st);
        }
        System.out.format("AV %d\n", (tt / 10000));
    }
}
Average time: 0.360 sec
```
Better Linear Search

- Same operations as LinearSearch
- if x is in A
  - on average will only look at 1/2 of A
  - time = $3t N / 2$
- If x NOT in A
  - no different from linear search
  - time = $3t N / 2$

**EXPECTATION:**
- if x is at least sometimes in A, then this will be faster than linearSearch

```python
procedure betterLinearSearch(A, n, x)

Inputs & Outputs: Same as Version 1

1. For each index $i = 0$ to $n-1$:
   a. If $A[i] = x$ then return value of $i$.
2. Return -1
```
Sentinel Linear Search

- Idea, guarantee search success so do not need to check $i < n$
- removes one operation from loop
- Time:
  - $x$ is in $A$: $2tN/2 \Rightarrow tn$
  - $x$ is NOT in $A$: $2tN$
- EXPECTATION:
  - regardless of whether $x$ is in $A$, this will be faster than linear search or better linear search.

```plaintext
procedure SentinelLinearSearch(A, n, x)
Inputs & Outputs: Same as Version 1
1. Last ← A[n-1]
3. Set i ← 0.
4. While A[i] ≠ x:
   a. Increment i by 1
5. A[n-1] ← Last
6. If i < n-1 or A[n-1] = x then return value of i.
7. Otherwise return -1
```
Hypotheses / Expectations

- If \( x \) is in \( A \),
  - better will be faster than basic
    - by about a factor of 2
  - sentinel will be faster than better
    - by about a factor of 1.5
- if \( x \) not in \( A \),
  - better will be the same as basic
  - sentinel will be faster than basic
    - by about a factor of 1.5
Test Procedure

Times when x is in A

- First size problem so times recorded are "large" enough
  - Why large times anyway?
- Java on my laptop
  - A length is 10,000,000
  - Number of searches is 300
    - Why not just 1 search over 3,000,000,000?

- Procedure:
  - Populate A with 10,000,000 random number in range 0..100,000,000
  - targets <= int[300]
  - for i in 0..300
    - rr = random(10,000,000)
    - targets[i] = a[rr]
Timing
Beware the Jabberwock!

```java
public class NanoT {
    public static void main(String[] args) {
        long l = System.nanoTime();
        long s = l;
        long t = 0;
        int c = 0;
        double d = 0.0;
        for (int i = 0; i < 10000000; i++) {
            long m = System.nanoTime();
            t += (m - l) / 10;
            c += (m - l) / 10.0;
            l = m;
        }
        long n = System.nanoTime();
        System.out.println(t);
        System.out.println((n - s)/10);
        System.out.println(d);
    }
}
```
Jabberwocky

By Lewis Carroll

’Twas brillig, and the slithy toves
Did gyre and gimble in the wabe:
All mimsy were the borogoves,
And the mome raths outgrabe.

“Beware the Jabberwock, my son!
The jaws that bite, the claws that catch!
Beware the Jubjub bird, and shun
The frumious Bandersnatch!”

....
Thoughts

- Times are roughly in line with expectations BUT
- basic - better outperforms
- better - sentinel underperforms

Why??
- could / should look deeper here but other topics seem more interesting

<table>
<thead>
<tr>
<th></th>
<th>Expected Speedup</th>
<th>Observed Speedup</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basic - better</td>
<td>2.0</td>
<td>2.7</td>
</tr>

<td>1.5</td>
<td>1.09</td>
</tr>
<tr>
<td>Basic - Sentinel</td>
<td>3.0</td>
<td>3.0</td>
</tr>
</tbody>
</table>
Linear search times when target is NOT in list

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Time in milliseconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>basic</td>
<td>1400</td>
</tr>
<tr>
<td>better</td>
<td>1450</td>
</tr>
<tr>
<td>sentinel</td>
<td>1350</td>
</tr>
</tbody>
</table>
Deeper thoughts

• Follows expectations / previous
  • better and basic essentially identical
  • sentinel better by about 1.1x

• BUT
  • times for basic between items are in and items are not in
    • In: 1920ms  Not In: 1420ms
    • Expectation: identical, results: 1.35x speedup on a set of numbers NOT in the list being searched
      • ARGGGGG
        • Why is "not in" so much faster for basic??
          • happens in java when: below range, above range (better is unaffected)
          • does not happen in java when: item is the last (ie the worst case test)
          • does not happen in Rust.
More Thoughts

- All data is average over 10 runs
- Select 10,000,000 randoms
- Select 300 targets
- For i in 1..10
  - run linear -- get time
  - run better -- get time
  - run sentinel -- get time
- So conditions are as identical as I can make them
Inconsistent Times

- Differences are small by they should be 0
- Why
  - 2 sources of inconsistency
    - Java
    - startup -- JVM issues
  - Other
  - Laptop
Inconsistent Times

Taken on a Lab machine

- Differences are smaller
  - Laptop a definite issue
  - Still have Java issues
  - Startup
  - Other
    - What is "other"

Time difference -- one run to the next
Hypothesis -- Garbage Collection

• Java has Garbage collection
• Garbage Collector runs when it chooses to run
• Realistically this program generates very little garbage, but ...
• Is this a testable hypothesis?
  • How?
    • Cannot just turn off GC
• Replicate in a language without GC?
Turning off CG

- Cannot be done in Java
- So replicate code in Rust
  - No java "startup" issue
  - Still inconsistent!
- Rust has a lot of debug stuff
  - Run for release??
Rust reports 0ms runtime

When compiled for release

```rust
fn f1w(search_in: &Vec<u64>, search_for:&Vec<u64>) -> (Duration, i32) {
    let now = Instant::now();
    for i in 0..search_for.len() {
        let mut found = false;
        let tgt = search_for[i];
        let mut ii = 0;
        while ii<search_in.len() {
            if search_in[ii]==tgt {
                found = true;
            }
            ii += 1;
        }
    }
    return (now.elapsed(), nfc);
}
```
Rust actually gets pretty stable

<table>
<thead>
<tr>
<th></th>
<th>Expected Speedup</th>
<th>Observed Speedup</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basic - better</td>
<td>2.0</td>
<td>1.35</td>
</tr>
<tr>
<td>Better - Sentinel</td>
<td>1.5</td>
<td>1.02</td>
</tr>
<tr>
<td>Basic - Sentinel</td>
<td>3.0</td>
<td>1.4</td>
</tr>
</tbody>
</table>

Time difference -- one run to the next

Is this a good chart??
Recursive Search

• Slow!!
• Stack Overflow!
  • java -Xss 1024000
    • 1MB the default
  • ~15000 before overflow at 1MB
• to get chart used 14M of stack space

Linear search times when target is in list
50,000 successful searches in a list for size 400,000
stack size increased to 14M
Tail Recursion Optimization

- basically rewrites recursion as a loop
- No stack overflow

- Very few procedural languages that have this
  - gcc -- with -O2 or higher
    - 2.16sec vs 0.000204sec -- 10000X speedup
    - more commonly <100x
  - kotlin -- if the function is marked for tail call optimization
Contributions

• Empirical results are roughly in line with Cormen and my theoretical analysis
  • primitive operations probably do NOT have equal cost
  • Whatever you code, the compiler might do something else!
• Empirical results are noisy
  • Java
    • startup effects
      • Ignore the first few results
  • GC
    • Always get averages over lots of samples
    • If possible, write code to minimize garbage generation
• Rust -- no startup, no GC but still some noise!
• Laptop effects
• Recursion
  • When you can, use a loop
  • When you cannot, worry about Stack Overflow

P = NP?

from wikipedia
NP-Complete

- NP = Non-deterministic Polynomial
- in NP == Solution is verifiable in P time
- problem is provably equivalent to other NP complete problems
• vertex cover of a graph is a set of vertices that includes at least one endpoint of every edge.
Vertex Cover Algorithm

- Find the minimum vertex cover of a graph
- We will discuss graph representations, just make something up for now
Vertex Cover Algorithms

- Optimal algorithm
- Naive algorithm
- Greedy Algorithm
• More on xkcd.com
An algorithm to consider

- Given two lists of integers
- call these A and B
- Find: min(abs(A[i]-B[j]))
